*Carriers generally do not experience symptoms.

No disease-causing mutations were detected in any other gene tested. A complete list of all conditions tested can be found on page 8.

CLINICAL NOTES

- DONOR is a carrier of one or more extra copies of the alpha globin gene on one chromosome. This alone is not expected to cause clinical signs or symptoms. However, individuals who have one or more extra copies of the alpha globin gene in combination with certain disease-causing *HBB* variants (beta-plus or beta-zero) may be at risk for a beta thalassemia intermedia phenotype. This phenotype is variable and may result in no symptoms. If not already performed, beta globin gene testing is recommended for a reproductive partner to assess the risk of having a child with beta thalassemia intermedia. Genetic counseling is recommended. See risk calculations at end of report for additional information.

NEXT STEPS

- Carrier testing should be considered for the diseases specified above for the patient's partner, as both parents must be carriers before a child is at high risk of developing the disease.
- Genetic counseling is recommended and patients may wish to discuss any positive results with blood relatives, as there is an increased chance that they are also carriers.

What are USH2A-related Disorders?

There are three types of Usher syndrome, identified as type I, type II, and type III. The different types of Usher syndrome differ in the severity and the age of onset. Mutations in the *USH2A* gene cause Usher syndrome type II.

Usher syndrome type II causes mild to severe hearing loss beginning at birth (congenital) and progressive loss of vision, typically beginning in adolescence or adulthood. The hearing loss with this form is usually not progressive and mainly affects the ability to detect high frequency sounds. The degree of hearing loss varies both among individuals and within families with Usher syndrome type II. Unlike other forms of Usher syndrome, Usher syndrome type II is generally not associated with balance problems.

Vision loss in Usher syndrome type II is due to a condition called retinitis pigmentosa (RP) and usually begins in the late teens or early twenties. The vision loss is progressive but does not usually lead to complete blindness. Typically the first sign of vision loss is night blindness that progresses to loss of peripheral (side) vision, eventually causing tunnel vision. This progression generally takes place over years or decades.

Some affected individuals have retinitis pigmentosa (RP) without hearing loss, a condition known as retinitis pigmentosa 39 (RP39).

How common are USH2A-related Disorders?

In the United States, Usher syndrome is conservatively thought to affect 4.4 in 100,000 people. The frequency of Usher syndrome type II is not known. Usher syndrome is likely responsible for 3-6% of all childhood deafness.

How are USH2A-related Disorders treated?

Currently there is no cure for Usher syndrome type II, but early treatment is important to give an affected child the best opportunity to develop communication skills. While a child is young, his or her brain is most receptive to learning language, either spoken or signed. Cochlear implants may improve hearing loss symptoms for some individuals. Specialists can introduce other tools and methods of instruction available to people with hearing loss. It is often helpful if the family undergoes such instruction together to help the child adapt.

Routine hearing and vision evaluations are important to detect potentially treatable complications, such as cataracts. Use of UV-A and UV-B blocking sunglasses and other low vision aids may ease the discomfort and difficulties associated with RP. Affected individuals are sometimes prone to accidental injury due to their vision loss and may need to devise systems to avoid such problems. Activities such as sports and driving a car may be difficult or dangerous. Therapy with vitamin A palmitate may slow retinal degeneration for some. Counseling and lifestyle therapy may help affected individuals cope with the difficulties associated with vision loss.

What is the prognosis for a person with an USH2A-related Disorder?

Although the hearing loss symptoms are moderate to severe, most children with Usher syndrome type 2A can use oral communication. Cochlear implants may improve hearing loss in some children. Symptoms of vision loss typically begin in late childhood or early adolescence and the narrowing of the visual field progresses over time. This condition is not associated with balance problems associated other types of Usher syndrome. Usher syndrome type II does not affect intellectual ability or life span.

What are ERCC6-related Disorders?

ERCC6-related disorders are more commonly known as Cockayne syndrome type B, an inherited disorder characterized by severe growth delay, a small head size, developmental delays, and intellectual disabilities. Other common features of the condition include an increased sensitivity to sunlight (photosensitivity), significant tooth decay, vision problems, and hearing loss. In addition, affected individuals may have certain facial features such a small chin, large ears, and a slender nose, which may make them appear older than their actual age.

ERCC6-related disorders are sometimes divided into three forms called Cockayne syndrome type I, Cockayne syndrome type II, and Cockayne syndrome type III. These forms differ in the age at which symptoms first appear and how fast the symptoms progress. However, the three forms are not completely distinct, with some patients having features consistent with more than one type.

Cockayne syndrome type I is the most common type of ERCC6-related disorder. Newborns with this type generally appear normal. However, their growth slows considerably within the first two years of life. With time, their length, weight, and head size are all significantly less than expected for their age. Affected children also develop vision and hearing problems that worsen over time, as well as neurological problems such as increased muscle tone, difficulty walking, tremors, seizures, feeding difficulties, and behavioral issues. Other possible symptoms include (but are not limited to) cataracts, frequent cavities, dry skin and hair, bone problems, and changes in the brain that can be seen on brain imaging.

Cockayne syndrome type II (sometimes called cerebro-oculo-facio-skeletal [COFS] syndrome or Pena-Shokeir syndrome type II) is the most severe form of the disease, with signs and symptoms appearing at birth or in the newborn period. Infants are small at birth and often have cataracts or other eye abnormalities (such as small corneas). With time, they continue to have significant problems with growth and severe developmental delays. Affected children are typically unable to speak and cannot sit or walk independently.

Cockayne syndrome type III is the mildest form of the condition, with symptoms appearing later in childhood. While affected children with this type have some of the features associated with Cockayne syndrome types I and II, their growth deficiency and developmental delays are not as severe.

How common are ERCC6-related Disorders?

It has been estimated that Cockayne syndrome affects approximately 1 in 200,000 Europeans each year. *ERCC6* accounts for 65% of individuals affected with Cockayne syndrome. Studies have also suggested that the condition may be more common in certain populations (such as the Druze population in Northern Israel) and that certain recurring *ERCC6* gene changes may be more common in individuals from Reunion Island and in some individuals of French or British ancestry.

How are ERCC6-related Disorders treated?

There is no cure for ERCC6-related disorders. Treatment is focused on managing the symptoms of the condition. This may include medication for muscle stiffness, tremors, or seizures, physical therapy or assistive devices for mobility issues, educational programs for intellectual disabilities, feeding tubes for those with significant feeding difficulties, hearing aids for those with hearing loss, and standard therapies for the treatment of cataracts or other vision problems. In addition, aggressive dental care will help minimize the risk of cavities and sun protection is necessary for managing photosensitivity, although exposure to excessive sunlight should be avoided. Metronidazole (a type of antibiotic) should also be avoided, as use of this medication can cause liver failure in individuals with Cockayne syndrome.

What is the prognosis for a person with an ERCC6-related Disorder?

The prognosis for ERCC6-related disorders varies depending on the type of Cockayne syndrome. Most individuals with Cockayne syndrome type I die by the age of 20, with an average age at death of 12 years. However, survival past the age of 20 has been reported. For those with Cockayne syndrome type II, the most severe form of the condition, death by age 7 is typical. The average life expectancy for those with Cockayne syndrome type III is not currently known.

Methods and Limitations

DONOR 10451 [Foresight Carrier Screen]: Sequencing with copy number analysis, spinal muscular atrophy, and analysis of homologous regions.

Sequencing with copy number analysis

High-throughput sequencing and read depth-based copy number analysis are used to analyze the listed exons, as well as selected intergenic and intronic regions, of the genes in the Conditions Tested section of the report. The region of interest (ROI) of the test comprises these regions, in addition to the 20 intronic bases flanking each exon. In a minority of cases where genomic features (e.g., long homopolymers) compromise calling fidelity, the affected intronic bases are not included in the ROI. The ROI is sequenced to high coverage and the sequences are compared to standards and references of normal variation. More than 99% of all bases in the ROI are sequenced at greater than the minimum read depth. Mutations may not be detected in areas of lower sequence coverage. Small insertions and deletions may not be as accurately determined as single nucleotide variants. Genes that have closely related pseudogenes may be addressed by a different method. *CFTR* and *DMD* testing includes analysis for both large (exon-level) deletions and duplications with an average sensitivity of 99%, while other genes are only analyzed for large deletions with a sensitivity of >75%. However, the sensitivity may be higher for selected founder deletions. The breakpoints of copy number variants and exons affected are estimated from probe positions. Only exons known to be included in the copy number variant are provided in the name. In some cases, the copy number variant may be larger or smaller than indicated. If *GJB2* is tested, two large upstream deletions which overlap *GJB6* and affect the expression of *GJB2*, del(*GJB6*-D13S1830) and del(*GJB6*-D13S1854), are also analyzed. Mosaicism or somatic variants present at low levels may not be detected. If detected, these may not be reported.

Detection rates are determined by using literature to estimate the fraction of disease alleles, weighted by frequency, that the methodology is unable to detect. Detection rates only account for analytical sensitivity and certain variants that have been previously described in the literature may not be reported if there is insufficient evidence for pathogenicity. Detection rates do not account for the disease-specific rates of de novo mutations.

All variants that are a recognized cause of the disease will be reported. In addition, variants that have not previously been established as a recognized cause of disease may be identified. In these cases, only variants classified as "likely" pathogenic are reported. Likely pathogenic variants are described elsewhere in the report as "likely to have a negative impact on gene function". Likely pathogenic variants are evaluated and classified by assessing the nature of the variant and reviewing reports of allele frequencies in cases and controls, functional studies, variant annotation and effect prediction, and segregation studies. Exon level duplications are assumed to be in tandem and are classified according to their predicted effect on the reading frame. Benign variants, variants of uncertain significance, and variants not directly associated with the intended disease phenotype are not reported. Curation summaries of reported variants are available upon request.

Spinal muscular atrophy

Targeted copy number analysis is used to determine the copy number of exon 7 of the *SMN1* gene relative to other genes. Other mutations may interfere with this analysis. Some individuals with two copies of *SMN1* are carriers with two *SMN1* genes on one chromosome and a *SMN1* deletion on the other chromosome. This is more likely in individuals who have 2 copies of the *SMN1* gene and are positive for the g.27134T>G SNP, which affects the reported residual risk; Ashkenazi Jewish or Asian patients with this genotype have a high post-test likelihood of being carriers for SMA and are reported as carriers. The g.27134T>G SNP is only reported in individuals who have 2 copies of *SMN1*.

Analysis of homologous regions

A combination of high-throughput sequencing, read depth-based copy number analysis, and targeted genotyping is used to determine the number of functional gene copies and/or the presence of selected loss of function mutations in certain genes that have homology to other regions. The precise breakpoints of large deletions in these genes cannot be determined, but are estimated from copy number analysis. High numbers of pseudogene copies may interfere with this analysis.

If *CYP21A2* is tested, patients who have one or more additional copies of the *CYP21A2* gene and a loss of function mutation may not actually be a carrier of 21-hydroxylase-deficient congenital adrenal hyperplasia (CAH). Because the true incidence of non-classic CAH is unknown, the residual carrier and reproductive risk numbers on the report are only based on published incidences for classic CAH. However, the published prevalence of non-classic CAH is highest in individuals of Ashkenazi Jewish, Hispanic, Italian, and Yugoslav descent. Therefore, the residual and reproductive risks are likely an underestimate of overall chances for 21-hydroxylase-deficient CAH, especially in the aforementioned populations, as they do not account for non-classic CAH. If *HBA1*/*HBA2* are tested, some individuals with four alpha globin genes may be carriers, with three genes on one chromosome and a deletion on the other chromosome. This and similar, but rare, carrier states, where complementary changes exist in both the gene and a pseudogene, may not be detected by the assay.

Limitations

In an unknown number of cases, nearby genetic variants may interfere with mutation detection. Other possible sources of diagnostic error include sample mix-up, trace contamination, bone marrow transplantation, blood transfusions and technical errors. This test is designed to detect and report germline alterations. While somatic variants present at low levels may be detected, these may not be reported. f more than one variant is detected in a gene, additional studies may be necessary to determine if those variants lie on the same chromosome or different chromosomes. The test does not fully address all inherited forms of intellectual disability, birth defects and genetic disease. A family history of any of these conditions may warrant additional evaluation. Furthermore, not all mutations will be identified in the genes analyzed and additional testing may be beneficial for some patients. For example, individuals of African, Southeast Asian, and Mediterranean ancestry are at increased risk for being carriers for hemoglobinopathies, which can be identified by CBC and hemoglobin electrophoresis or HPLC (*ACOG Practice Bulletin No. 78. Obstet.Gynecol. 2007;109:229-37*).

Risk Calculations

Below are the risk calculations for all conditions tested. Since negative results do not completely rule out the possibility of being a carrier, the **residual risk** represents the patient's post-test likelihood of being a carrier and the **reproductive risk** represents the likelihood the patient's future children could inherit each disease. These risks are inherent to all carrier screening tests, may vary by ethnicity, are predicated on a negative family history and are present even after a negative test result. Inaccurate reporting of ethnicity may cause errors in risk calculation. The reproductive risk presented is based on a hypothetical pairing with a partner of the same ethnic group.

†Indicates a positive result. See the full clinical report for interpretation and details.
